The filtering operations filters the given stream and returns a new stream, which contains only those elements that are required for the next operation.

filter() method

The Stream interface has a filter() method to filter a stream. This is an intermediate operation. Below is the method definition of filter() method.

```
Stream filter(Predicate<? super T> predicate)
```

Parameter -> A predicate to apply to each element to determine if it should be included.

Return Type -> It returns a stream consisting of the elements of this stream that match the given predicate.

```
import java.util.ArrayList;
   import java.util.List;
   import java.util.stream.Stream;
   public class StreamDemo {
 5
       public static void main(String[] args) {
            //Created a list of integers
           List<Integer> list = new ArrayList<>();
10
            list.add(1);
11
12
            list.add(12);
            list.add(23);
13
14
            list.add(45);
            list.add(6);
15
16
            list.stream()
                                                    // Created a stream from the list
17
                    .filter(num -> num > 10)  //filter operation to get only numbers greater than 10
18
                    .forEach(System.out::println); // Printing each number in the list after filtering.
19
20
21
            //Again printing the elements of List to show that the original list is not modified.
            System.out.println("Original list is not modified");
22
            list.stream()
23
                    .forEach(System.out::println);
24
25
26
27
Run
                                                                                                  Reset
```

1. Create a stream from our list.

In the above example, we created a list of integers. We followed the below steps:

2. Apply a filter() operation on this stream. We want to print only those numbers which are greater than

import java.util.ArrayList;

10, so we add a filter.

filter() with custom object#

Please note that the filter operation does not modify the original List.

Let's look at another example of filter() with a custom object.

In the below example, we are using multiple conditions in the filter method.

```
import java.util.List;
       public class StreamDemo {
           public static void main(String[] args) {
               //Created a list of Person object.
               List<Person> list = new ArrayList<>();
               list.add(new Person("Dave", 23));
               list.add(new Person("Joe", 18));
   10
               list.add(new Person("Ryan", 54));
   11
               list.add(new Person("Iyan", 5));
   12
               list.add(new Person("Ray", 63));
   13
   14
   15
               // We are filtering out those persons whose age is more than 18 and less than 60
   16
                list.stream()
                        .filter(person -> person.getAge() > 18 && person.getAge() < 60)</pre>
   17
                        .forEach(System.out::println);
   18
   19
   20
   21
   22
       class Person {
   23
   24
           String name;
   25
           int age;
   26
   27
           Person(String name, int age) {
   28
               this.name = name;
   Run
                                                                                                       Reset
In the above example, we used multiple conditions inside our filter.
```

In the above example, we wrote all the conditions in a single filter.

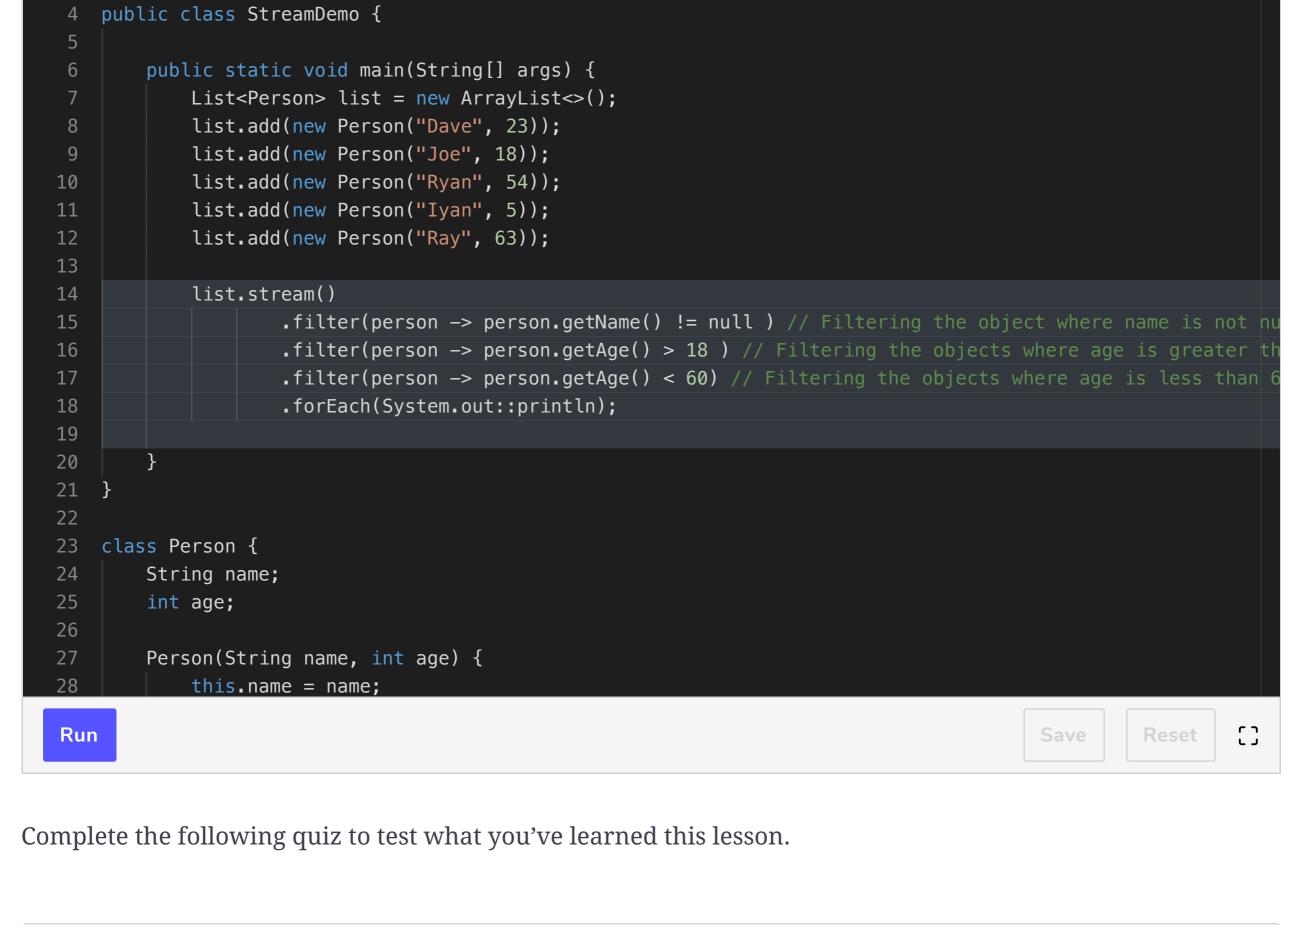

We can also chain the filter method to make the code more readable.

import java.util.List;

3

filter() chaining

1 import java.util.ArrayList;

C

1	Which of the following is true about the filter() method? Choose all that apply.	
	A) It is an intermediate operation.	
	B) It takes a Function as a parameter.	
	C) It takes a Predicate as a parameter.	
	D) None of the above.
